

The mass A attempts to dock with the mass B . Their masses are $m_A = 18 \text{ kg}$ and $m_B = 6.6 \text{ kg}$. The mass B stationary relative to the reference frame, and the mass A approaches velocity $\mathbf{V}_A = (0.2 \hat{i} + 0.3 \hat{j} - 0.02 \hat{k}) \text{ m/s}$.

- If the first attempt at docking is successful, what is the velocity of the centre mass of the combined masses afterwards?
- If the coefficient of restitution of resulting impact is $e = 0.95$, what are the velocities of the two masses after impact?

(a)

$$\mathbf{V} = \frac{m_A \mathbf{V}_A + m_B \mathbf{V}_B}{m_A + m_B} = \frac{18(0.2 \hat{i} + 0.3 \hat{j} - 0.02 \hat{k}) + 6.6 \times 0}{18 + 6.6}$$

$$= 0.1463 \hat{i} + 0.2195 \hat{j} - 0.0146 \hat{k} \frac{\text{m}}{\text{s}}$$

$$\boxed{\mathbf{V} = 0.1463 \hat{i} + 0.2195 \hat{j} - 0.0146 \hat{k} \left(\frac{\text{m}}{\text{s}}\right)}$$

(b) The y and z component of the velocities of both masses are unchanged.

To determine the x components, we use conservation of

linear momentum.

$$m_1(v_A)_x + m_2(v_B)_x = m_1(v'_A)_x + m_2(v'_B)_x \Rightarrow$$

$$18(0.2) + 6.6 \times 0 = 18(v'_A)_x + 6.6(v'_B)_x \Rightarrow$$

$$\boxed{(v'_A)_x + 6.6(v'_B)_x = 3.6} \quad (1)$$

$$e = \frac{(v'_B)_x - (v'_A)_x}{(v_A)_x - (v_B)_x} \Rightarrow 0.95 = \frac{(v'_B)_x - (v'_A)_x}{0.2 - 0} \Rightarrow$$

$$\boxed{-(v'_A)_x + (v'_B)_x = 0.19} \quad (2)$$

$$\begin{cases} 18(v'_A)_x + 6.6(v'_B)_x = 3.6 \\ -(v'_A)_x + (v'_B)_x = 0.19 \end{cases} \Rightarrow \begin{cases} (v'_A)_x = 0.0954 \frac{m}{s} \\ (v'_B)_x = 0.2854 \frac{m}{s} \end{cases} \quad \text{*} \quad (3)$$

So the velocities of the masses after the impact are

$$\begin{cases} v'_A = (0.0954 \hat{i} + 0.3 \hat{j} - 0.02 \hat{k}) (\frac{m}{s}) \end{cases}$$

$$\begin{cases} v'_B = 0.2854 \hat{i} (\frac{m}{s}) \end{cases}$$
